

## Data Base Engineering

### Intro to DBS

- \* Data : Data are known facts that can be recorded and have implicit meaning.
- ⇒ Database (DB) : collection of related data relevant to a particular enterprise.
- ⇒ DBMS : is a collection of interrelated data and a set of programs to access those data.
- ⇒ file vs DB system

#### file system

- It leads to data redundancy and inconsistency which results in higher storage cost and access cost.
- Causes difficulty in accessing data efficiently.

→ Integrity problems are created becos of consistency constraints.

→ Atomicity is difficult to ensure.

→ concurrent access anomalies occurs becos data may be accessed uncoordinated application programs.

→ security constraints are difficult to ensure as applications are added in an adhoc manner.

#### ~~problem with file system~~

1. data redundancy & inconsistency
2. difficulty in reading & accessing data
3. Isolation problem
4. Integration problem
5. Atomicity problem
6. security problem
7. concurrency anomalies

WV

Data Abstraction

to hide the complexity of the system from the end user the developer use three level of abstraction :-

## (i) physical level

It describes how the data is actually stored.

(ii) logical level - It describes what data is stored and inter-relationship b/w all them.

(iii) The view-level, It provides many views of the same data base alongwith security and restricted access.

Instance & Schema :

The schema is the overall design and logical structures of the data base. The schema is rarely changed.

The instance is a collection of information stored in the data base at any particular moment and it also called extension

Data Models

is a collection of conceptual tools for describing data, the relationship semantics and constraints

## (i) Relational Model / Record Based Model

It represents data and the relationship b/w them using a collection of tables having fixed format records and attributes.  
e.g oracle db, MySQL server

## (ii) Entity Relationship(ER) model

It is based on a collection of objects called entities and the relationship b/w them.

## (iii) Object Based data model

It is an extension of ER model with the concept of objects, methods and encapsulation.

## (iv) Semi-Structured data Model

It is used to represent individual data item of the same type that may have different set of attributes.

10/01/2018

relational dB system use SQL to query and manipulate data.

⇒ Naive Users: are unsophisticated user who interact with DB using an application.

⇒ Application Programmers:  
They develop user interfaces using RAD tools

⇒ Sophisticated Users:  
They interact with the system without writing programs using a query language and they are internal to the organisation.

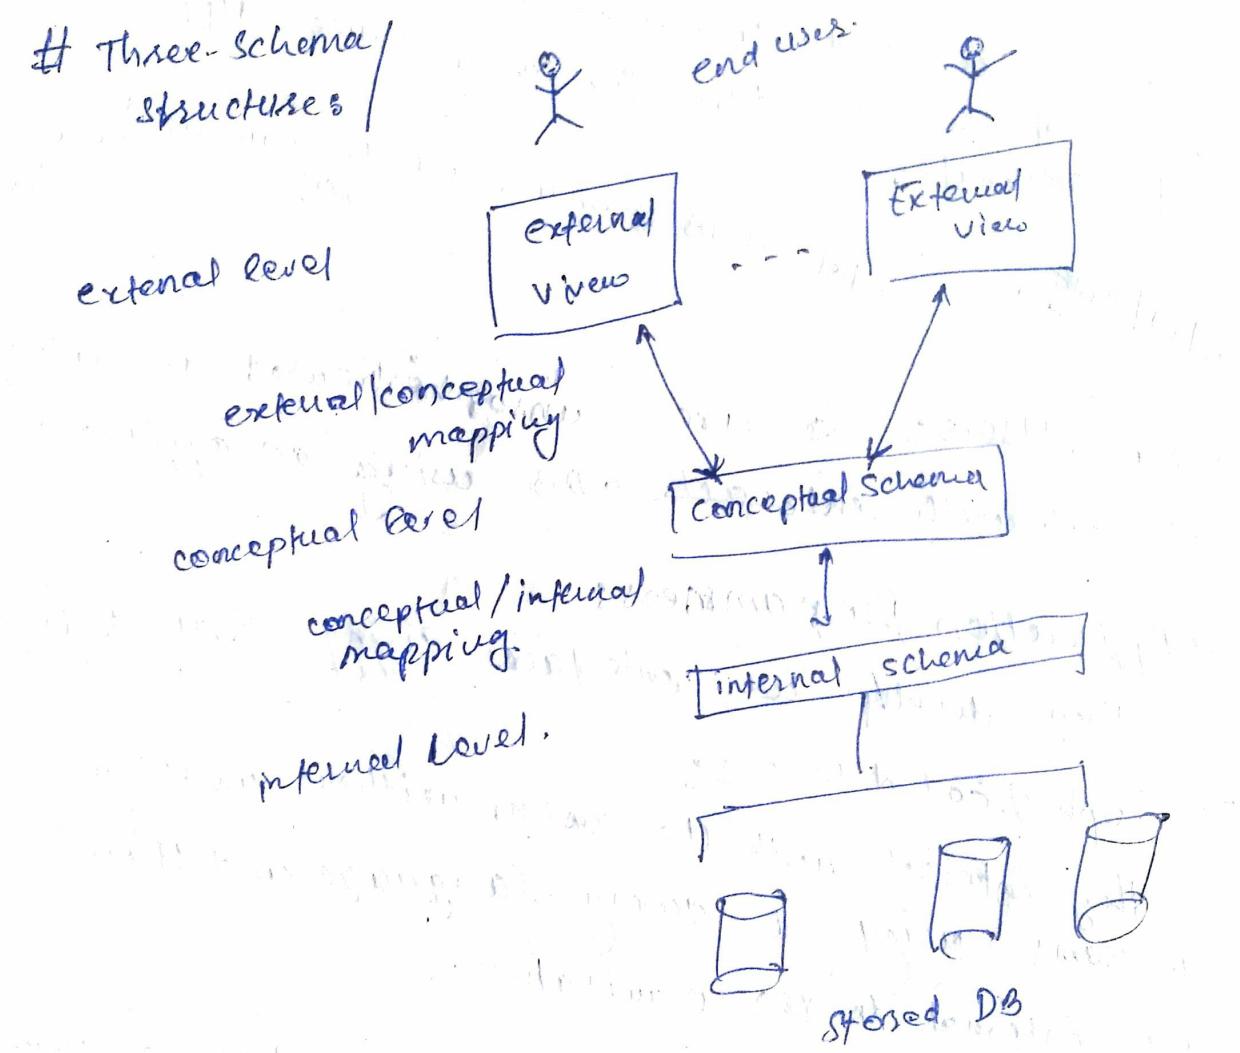

⇒ Specialised User: write special data base applications like knowledge based system and expert system.

## # Function of DBA (DB administrator)

- It defines the storage structures and access methods.
- It reorganises the schema to reflect changes or improve performance.

- Granting of authorization to users for data access
- Routine Maintenance like taking periodic backup to remote servers and disks
- The DBA ensures enough disk space for normal operation and monitors jobs for system performance.

## # Three-Schema/ structures

⇒ External level: It describes the part of the database that a particular user is interested and hide the rest.

⇒ Conceptual Schema: It describes what data is present and stored in the DB and the relationships b/w them.

⇒ internal/physical level:  
Describes, how the data is stored using physical storage structure.

12/01/18

Data Independence: The three schema architecture implements data abstraction which leads to data independence. It is the capacity to change the DB schema at one level without having the DB schema to change at next higher level.

Logical DI: is the ability to change the conceptual schema without having to change the external schema.

Physical DI: ability to change the physical schema without having to change the conceptual schema.

Classification of DBMS:

Based on Data Models

- ① Hierarchical Model
- ② Network model

Based on no. of users

- (i) single users
- (ii) multiusers

Based on the no. of sites:

i) centralized

All data is located in one server

(i) Distributed

The data and the DBMS is distributed over many sites using communication network

(ii) Homogeneous: Uses the same set of SW in multiple location

iv) Heterogeneous: In heterogeneous syst the DBMs have diff'nt set of SW, OS and HW at multiple locations.

Based on Domain:

i) General Purpose DBMS:

e.g., Domain specific ERP.

ii) Special Purpose DBMS

this syst have to support large no. of concurrent transactions without accessing excessive delays.

also called OLTP syst  
Online Transaction Processing

Q. Create an instance & schema for the following.

customer ( cust\_name, cust\_id, address)

Bank ( name, IFSC code, location )

loan ( loan no, Bank name, cust\_id ).

customer

cust_name	cust_id	address
A	1	B <sub>2</sub>
B	2	B <sub>3</sub>

Bank

name	IFSC code	location
BA	B1D	B <sub>23</sub> B <sub>ABC</sub>
BC	B1I	B C D

loan

loan no.	Bank name	Cust id
011	BA	1
012	BC	2

customer

cust_name	cust_id	address
A	1	B <sub>2</sub>
B	2	B <sub>3</sub>

Bank

name	IFSC code	location
BA	B1D	B <sub>23</sub> B <sub>ABC</sub>
BC	B1I	B C D

loan

loan no.	Bank name	Cust id
011	BA	1
012	BC	2

16/02/18

ER Modeling: It describes data as entities attribute and represents the logical relationships structure of the database.

# Entity: is an object or thing in real world which has independent existence  
e.g; student → concrete/physical

e.g file, room. ↕ Abstract / concept

Entity Set: It is a set of entities of the same type that share the same properties or attributes.

The individual entity of a set are called extensions of that set

Attributes: are descriptive properties of an entity and the set of permitted values for each attribute is called domain set.

# Types of Attributes: i) Simple (Atomic) Vs Composite

Atomic attributes are those that can not be divided into subparts and composite attributes can be divided into subparts.

# Single value Vs Multivalue

Single valued attributes have a single value for a particular entity and multi valued attributes have a set of values for a particular entities.

## # stored vs derived attributes

The value of a JFO derived attributes can be obtained from value of other stored attribute.

e.g; DOB is stored

Age is derived

## # NULL attributes

NULL attributes takes a null value when a particular entities does not have a value for it.

## # complex attributes: ~~composition of composite and multi valued~~

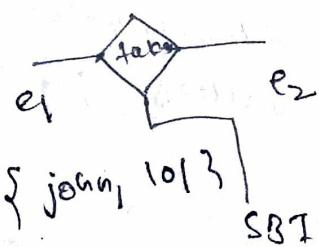

Relationship: It is an association among several entities and relationship set is a mathematical relation among  $n \geq 2$  entities taken from entity set

$$\{ (e_1, e_2, e_3, \dots, e_n) \mid e_1, e_2, e_3, \dots, e_n \in E_1, E_2, \dots, E_n \}$$

where  $(e_1, e_2, \dots, e_n)$  is a relationship

$E_1$   
Customer  
John

$E_2$   
Loan  
101

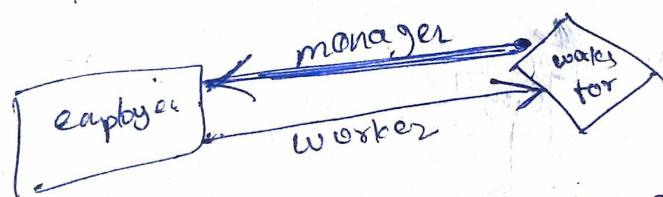

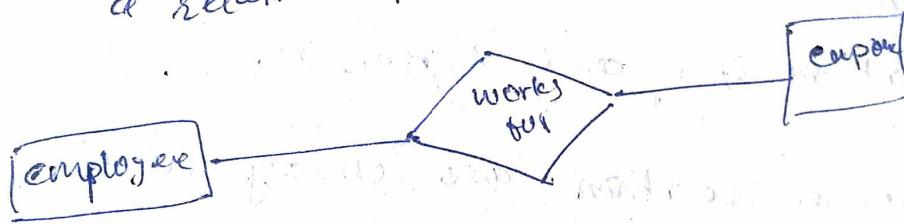

{John, 101, SBT} → takes loan

The association b/w entity sets is known as participation of the entity sets where  $E_1, E_2, \dots, E_n$  participates in a relationship  $R$  and relationship instance represents an association b/w the named entities.

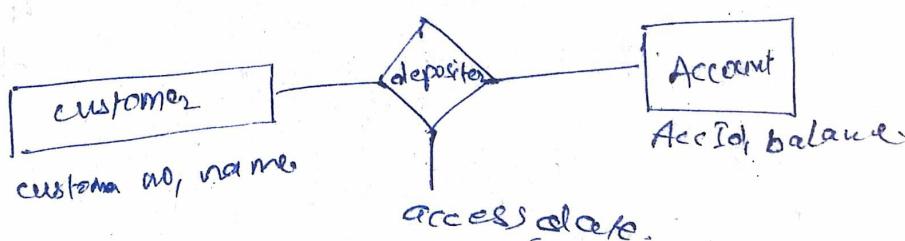

~~17/11/18~~  
Recessive Relationships

When a entity sets of a relationship set is not distinct then the entities role is defined.

→ Role is the fn that an entity plays in a relationship.

→ Relationship sets with attributes:  
A relationship may have attributes called descriptive attributes.

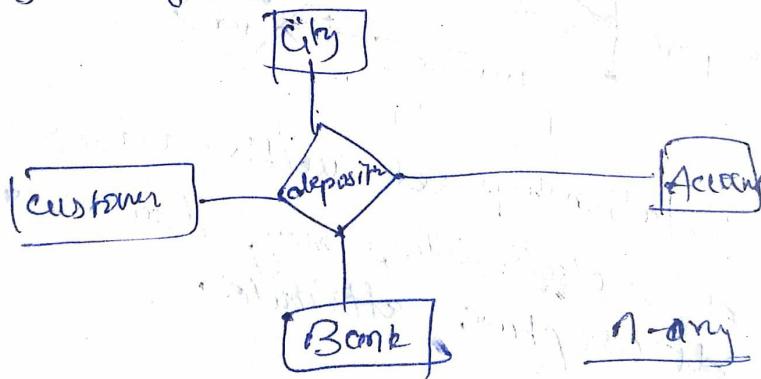

Degree of Relationship set :— the no. of entity sets that participate in a relationship set is called the degree of the relationship set. A relationship set that involves two entity sets is called binary relationship and has a degree of two.

If the no. of entity set is 3, the relationship is called ternary and the degree is 3.

If the no. of entity set is greater than three ( $n > 3$ ) it is called n-ary relationship, and degree  $n$ .

- \* Recursive relation are unary relation with a degree of 1.

constraints:

→ Mapping cardinality

→ key constraint

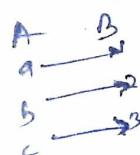

→ participation constraint

constraint constraints are the limitation to which the contents of the relationship must conform.

conformity also called

⇒ Mapping cardinality ratios express the no. of cardinality ratios express the no. of entities for which another entity can be associated within a relationship set.

1 to 1: An entity in A is associated with at most 1 entity in B and vice-versa.

e.g. persons driving license  
persons passport

1 to many:

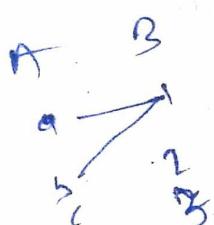

An entity in A is associated with any no. of entities in B but an entity in B is associated with max one

e.g. person phone no.

Many to 1: An entity in A is associated with at most one entity in B but

an entity in B can be associated with any no. of entities in A.

Many-Many: An entity in A is associated with any no. of entity in B and vice-versa.

## Key Constraints:

A key allows to identify a set of attributes such that they can uniquely identify an entity where these ~~can't~~ can't be two entities  $e_1$  and  $e_2$  where

$$e_1(a_1) > e_2(a_1)$$

$$e_1(a_2) = e_2(a_2)$$

$$e_1(a_3) = e_2(a_3)$$

Superkey: If an entity set is a combination of one or more attributes whose values uniquely determines each entity of the set.

19/11/18

Candidate key: of an entity set ~~of~~ is a minimal super key for which no proper subset is a super key. There might exist several candidate keys for a single table.

## Keys for Relationship sets:

$$\text{PK}(R) = \text{PK}_{E_1} \cup \text{PK}_{E_2} \cup \text{PK}_{E_3} \dots \cup \text{PK}_{E_n}$$

Employee (ename, empno, telno, deptno, deptname, address)

Dept (dname, did, dno)

Job (jname, jid, did)

superkey:

{ename, telno}, {jid, empno}, {allocation, dname},  
 {ename, telno}, {jid, jname},  
 {dno}, {jid, jname}

base is  $\text{PK} + \text{SPK}(R) = \{\text{empno}, \text{jid}, \text{dno}\}$

③ participation constraints:  
 if every entity in E, participates in at least one relationship in R. The participation is called total. But if some entities in E participate in relationship R then the participation is partial.

### WEEK ENTITY SETS

An entity set that does not have a primary key and is existence dependent on an identified entity set is called the week entity set.

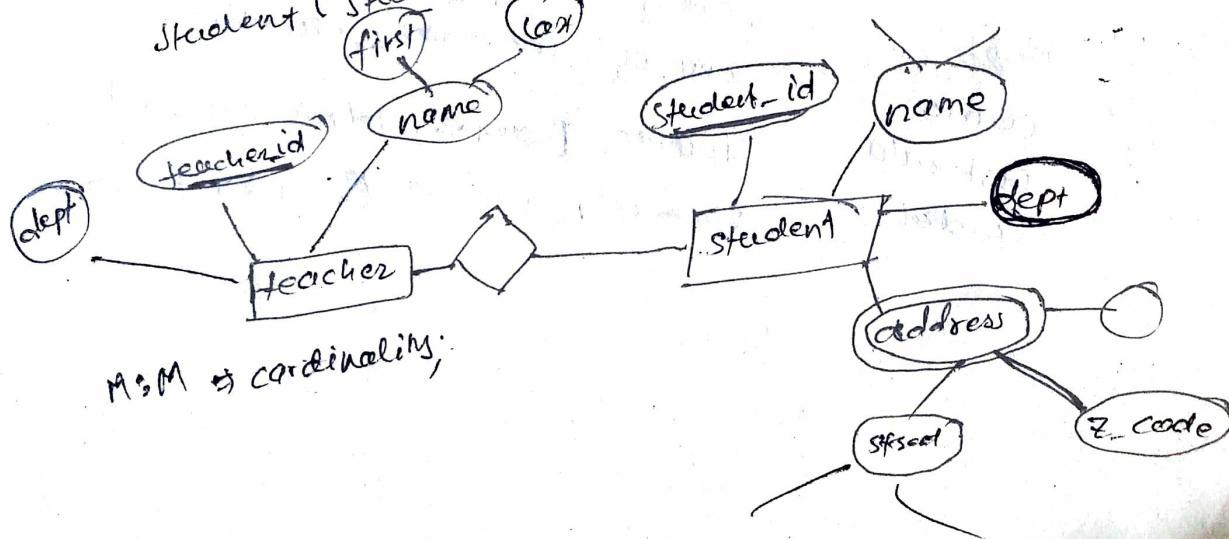

The primary key of a week entity set is formed by the strong entity set on which it is existence dependent and the discriminator of week entity set.

The discriminator is the attribute or set of attributes that distinguishes among the entity of the week entity set.

example: consider a teacher student relationship

Teacher(teacher-id, name, dept)

Student(student-id, name, dept, address).

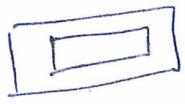

~~23/08/18~~

## ER notation

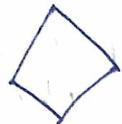

entity

weak entity

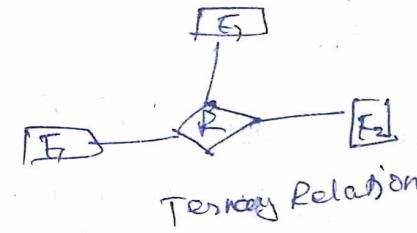

relation

total participation

partial participation

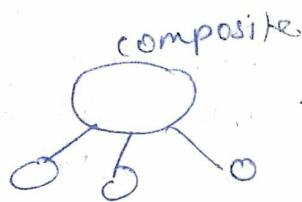

Tertiary Relation

Attribute

primary key

multivalued attribute

derived attribute

## Developing ER diagram

Step 1: Identify the entities

Step 2: find the relationships

Step 3: find the attributes

entity

Dept

course

instructor

student

Attributes

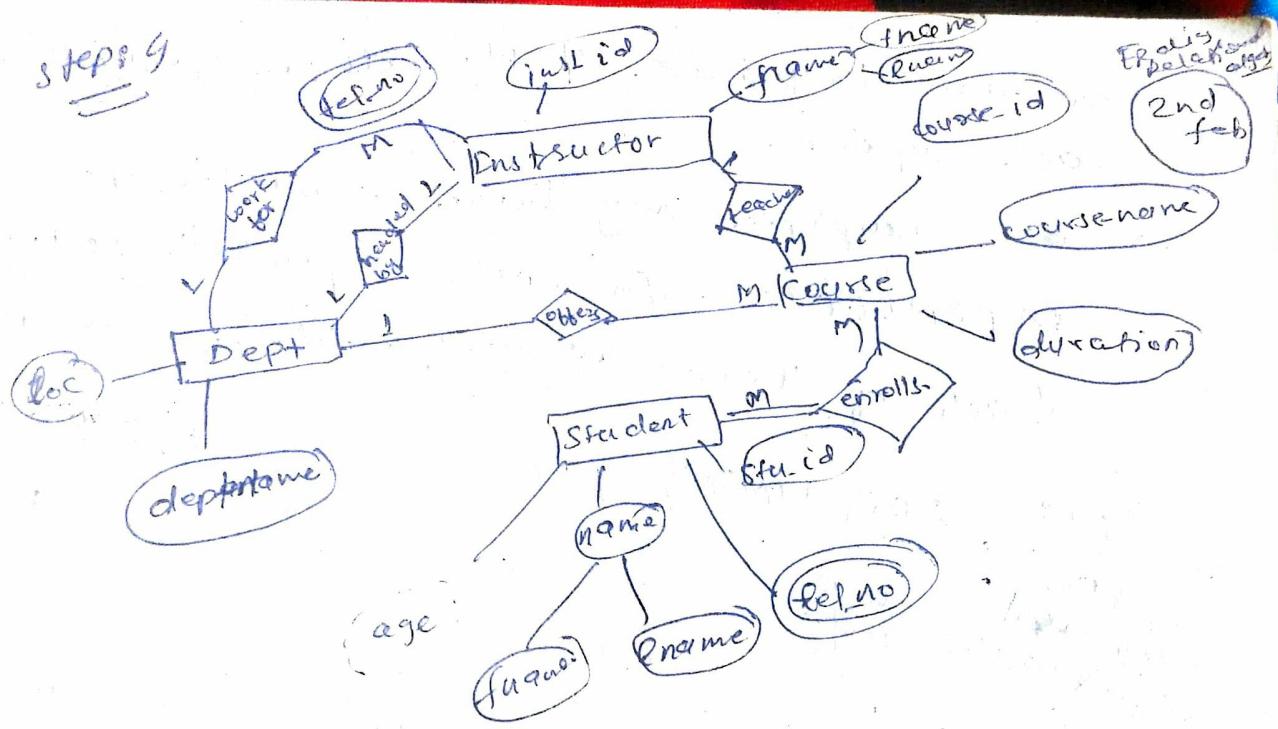

deptname, loc

courseid, coursename, duration

inname, iname, telno, inst\_id

stud\_id, fname, lname, telno, age

steps 4

### Company DB

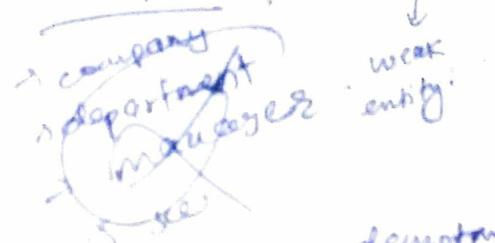

Requirements of the company:

- The company is organised onto DEPARTMENTS.
- each department has a name, number, location and an employee who manages the department and we keep track of the start date of the department manager.
- each department controls a number of PROJECTS. Each project has a name, number and is located at a single location.
- We store each EMPLOYEE's name and birth date, social security number, address, salary, name and birth date.
- Each employee works for one department but may work on several projects.
- we keep track of the number of hours course per week that an employee currently works on each project.

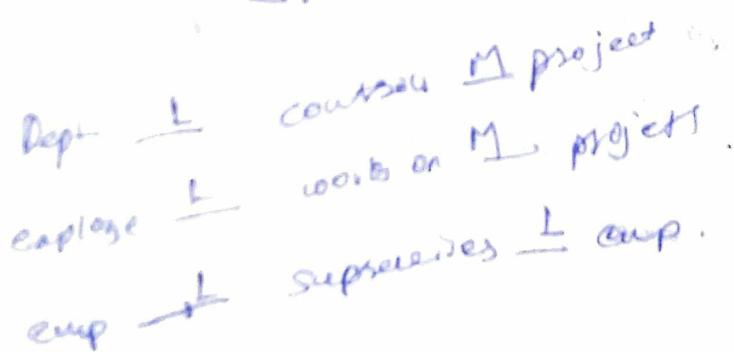

→ we also keep track of the direct supervisor of each employee.

→ each employee may have a number of DEPENDENTS. For each dependent, we keep track of their name, address, birth date

Step 1: @ DEPARTMENT, PROJECT, EMPLOYEE, DEPENDENT

department	1 : M	projects	controls
employee	1 : 1	department	works for
employee	1 : M	project	works on

30/11/8

## construction of ER Diagram :-

1. First we have to identify entities.
2. Then we have to identify attributes.
3. Then we have to identify relationships.
4. Finally we have to draw the ER diagram.

## Extended features of ER diagram:

1. Specialization  $\Rightarrow$  designating subgroup  
It is a process of entity set that are distinctive from each other in the set. The subgroups become the lower level entity set where the lower level entity set is called subclass and the higher level entity set called the superclass.

$\Rightarrow$  Generalisation & specialisation

$\Rightarrow$  top down process

$\Rightarrow$  bottom up process

$\Rightarrow$  focuses on similarities b/w attributes

$\Rightarrow$  focuses on difference b/w the attributes

$\rightarrow$

$\Rightarrow$  Attribute inheritance - a lower level entity set inherits all the attributes and relationships of the higher level entity set to which it belongs alongwith distinct feature within a particular level.

$\Rightarrow$  Design constraints  $\Rightarrow$  condition defined or user defined

$\Rightarrow$  also known as attribute define

$\Rightarrow$  membership is evaluated on the basis of

$\Rightarrow$  whether or not an entity satisfies an explicit cond or predicting

User defined? the data base administration  
assigns a particular entity into a given lower level entity set.

Disjoint:

This constraint requires that an entity belongs to no more than one lower level entity set and the overlapping constraint requires that same entity may belongs more than to one lower level entity set within a single generalization.

→ completeness constraint specifies whether or not an entity in the higher level entity set must belong to at least one of the lower level entity set within a generalization.

Total constraints: Each higher level entity set must belong to a lower level entity set and partially entity set is some higher level entity may not belong to any lower level entity set.

Aggregation: is an abstraction through which relationship are treated as higher level entities where it is convenient to express ~~among~~ relationship among relationships.

~~31/11/18~~

## Data Structures

### 2. Data Integrity

### 3. Data Manipulation

### 1. Data Structure

→ Relation: It is a representation of data and relationship in a 2D table.

→ Tuple → It is a particular row of a relation.

→ Attribute → It is a named column of a relation.

→ Domain: defines the kind of data or the set of all possible values that an attribute may contain.

→ Degree = is the no. of attribute in a relation.

→ Cardinality is the no. of tuple a relation contains.

### ① Data Integrity

→ keys

→ constraints

→ ER conversion into schema.

Data Integrity: It is enforced through relational keys and constraints, which ensure that the data is accurate and allows the specified operation to be performed on the data.

key's:

- ① Candidate key of a relation are those attribute which have the property of uniqueness and irreducibility, i.e. reducibility at any instance of time no two tuple are duplicate of each other for that attribute.

→ if a candidate key is composite key then no individual attribute of the candidate key is unique.

- ② superkey: Must satisfy the uniqueness property but may not satisfy the irreducibility property.

- ③ primary key: An attribute or set of attributes that uniquely identifies specific instances of an entity. It must satisfy the following properties:

- it must not contain null values.
- the value of the primary key should not change.
- The primary key must be visible to anyone who can create, read or delete a second record.

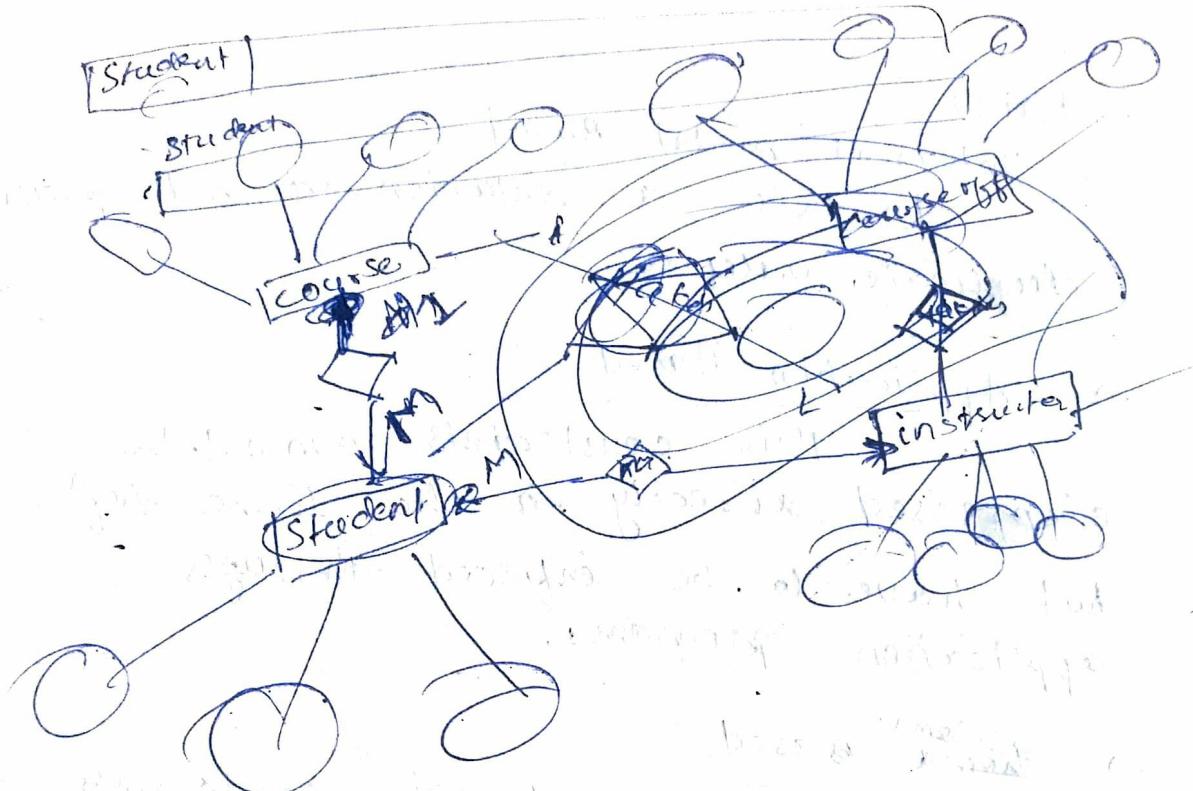

4. Alternate key: Are those keys from the list of candidate keys which are not selected as primary key.

5. foreign key: Are attributes of a table which refer to the primary key of some other table and are also known as referential integrity constraints.

a set of attributes  $f_k$  in its relation schema  $R_1$   
is a foreign key of  $R_2$  that references the  
relation  $R_2$  if it satisfies the following  
two conditions:

- ① the attribute  $f_k$  has the  
same domain as the primary  
key attribute  $P_k$
- ② The value of  $f_k$  in a tuple  $T_1$   
of  $\delta: \delta(R_1)$  either occurs as a  
value of  $P_k$  of some tuple  $T_2$  of  
 $\delta_2(R_2)$  or  $f_k$  is null.

A university registration office maintains data  
about the following entities:  
→ courses, including number, title, credits, syllabus,  
and prerequisites.  
→ course offering, including course number, year,  
semester, section number, instructors, timing and  
classroom.  
→ students, including student-id, name and  
program.  
→ instructor, including identification number, name,  
department, and title.  
→ further, the enrollment of students in courses  
and grades awarded to students in each  
course they are enrolled, instructors teaching  
courses for must be appropriately modeled.

example of a directed graph of a relationship

Directed graph ①

Students → Courses → Instructors → Courses

Students → Instructors → Courses

Students → Courses → Instructors

Students → Instructors → Courses

Students → Courses → Instructors

Students → Instructors → Courses

16/2/18

### Constraints:

→ Inherent model based

In this, a relation can not have duplicate values.

→ Application Based

This constraints can not be expressed directly in the schema def but have to be enforced through application programs.

→ Schema Based

These are domain constraints, keyconstraints, not NULL constraints and referential integrity constraints.

Reduction of ER diag. to Relation schema

i) Mapping strong Entity sets

ii) Mapping a composite attribute

composite attribute only their simple component in the resulting schema.

iii) Mapping a multivalued attributes  
it becomes a separate table with take a foreign key taken from the superior entity.

## n) Mapping a weak entity set

If be come a separate table with a foreign key taken from the strong entity set. The primary key of the weak entity set is composed of the discriminator of the weak entity set and the primary key of the strong entity set on which it is existence dependent.

## Representing Relationship set as table / schema.

① 1-M (one-many)  
the primary key of the 'one' side become the foreign key of the 'm' side

② M-M  
Create a new table for the relationship set with the primary key of the two entities as its own primary key.

student	sid   sname
---------	-------------

course	coid   cname
--------	--------------

registration

registration	sid   cid   date
	PK.

: Binary (1:1) relationship

total - partial

The PK of the partial side become the foreign key (FK) of the total side.

⇒ the FK of the total side will be a synonym for the PK of the partial side.

total - total or partial - partial

when there is total - total or partial - partial participation on both sides, the PK of the either of the entity becomes the FK of the other entity.

7/2/18

Mapping on Unary

1:M relationship  
the resulting table has the primary key attribute as the foreign key of the same table with the mandatory use of synonyms.

conversion of ternary relationship :-

## mapping extended ER features:

for the super type of each

- (ii) assign to the subtype those attribute which are unique to each subtype.

→ assign to the subtype, the primary key of the super type table.

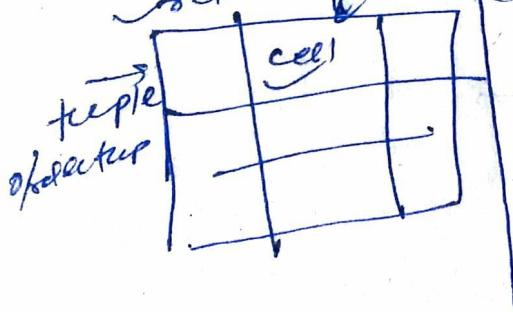

## Properties of a relation:-

Properties of a relation:-

- ① A rel is defined as a set of tuples where no preference is given for the logical ordering of elements in a selection.
- ② Ordering of values within a tuple must be maintained.
- ③ Avoid plotting null values as much as possible as they lead to wastage of memory.

## properties of Reln

- Reln name is not any where in else in the reln
- each attribute has distinct name & order of reln name & attrbts

## Data Manipulation

→ Relational Algebra

→ relational calculus

insert  
update  
delete  
more

It is a procedural lang. used to tell the db system how to build a new rel' from one or more existing rel' and it forms the basis of a query lang.

① select( $\sigma$ ): it is unary opes'

notation:  $\sigma_P(r)$

the operator selects tuples that satisfy a given selection predicate  $P$  and is defined as,

$$\sigma_P(r) = \{ t \mid t \in r \text{ and } P(t) \}$$

Select \* from loan where

branch = 'BSR'

branch = 'BSR'

e.g.  $\sigma_{(loan)} \text{ and } t_1 > 1200 \text{ and } branch = 'BSR'$

→ connectives are used for one predicates where

and  
or  
not

adding parentheses

will tell the db system which part to do first

eg.  $(t_1 > 1200) \text{ and } branch = 'BSR'$

will tell the db system which part to do first

### ② Project (Π) :

In the projection operation the result is defined as a selection of K columns obtained by erasing the columns that are not listed and eliminating the duplicate rows from the result.

$$\Pi_{A_1, A_2, \dots, A_k} (r) \quad \left\{ \begin{array}{l} A_1, A_2, \dots \text{ Attribute name} \\ r \rightarrow \text{relation name} \end{array} \right.$$

e.g; 1. select the names & salary of all the employee.

$$\Pi_{\text{name}, \text{sal}} (\text{emp})$$

$$2. \quad \Pi_{\text{name}, \text{sal}} (\text{emp}) \quad \xrightarrow{\text{emp}} \quad \text{set} > 2000 \quad \text{deptno} = 10,$$

③ Rename operation : allows to name the results of a relational algebra expression and also individual column.

$$\Rightarrow P_x(E)$$

④ Union operation : The union operation takes two relation E and S as input and gives the result p where p = r ∪ s which has tuples drawn from E and S such that they are either in E or S.

notation      r ∪ s

$$\text{defined as: } r \cup s = \{ t \mid t \in r \text{ or } t \in s \}$$

⑤ Set Difference Operation: takes two relations  $r$  and  $s$  as input and results in a relation where the tuple belongs to  $r$  but not  $s$ .

⑥ Set-Intersection Operation: takes two rel<sup>n</sup> as input and results in relation where the tuple must belong to  $r$  and  $s$ .

$$r \cap s = r - (r - s)$$

set of those elements which are present in  $r$  and not in  $s$ .  
→ this is also called set-difference operation.

Assumptions of Union, Intersection and Set Difference

- $r$  and  $s$  must have the same arity
- the attribute must be comparable i.e; the domain of the  $i$ th attribute of  $r$  must be same as the domain of  $i$ th attribute of  $s$ .

Properties of Union, Intersection and Set Difference

- both Union and Intersection are commutative
- Both  $(U, \cap)$  can be treated as associative
- Both  $(U, \cap)$  is applicable to any number of relations.
- the set difference operation is not commutative.

⑤ Cartesian Product: take two input relation  $r$  and  $s$  and result is a relation  $r \times s$  containing tuples  $t_r$  and  $q_s$ .

disadvantages: overloads the oracle engine

- Not a relevant method
- Results in spurious tuple

Banking example

branch (branch-name, branch-city, assets)  
customer (customer-name, customer-street, customer-city)  
account (account-number, branch-name, amount)  
depositor (customer-name, account-number)  
loan (loan-number, branch-name, amount)

R.Q) find all loans of over \$1200

(loan)

amount > 1200

or find the loan number for each loan of an amount greater than 1200

(loan)

loan-number (amount > 1200)

or find the names of all customers who have

a loan, an account, or both from the bank

or customer-name (borrower) OR customer-name (depositor)

or find the names of all customers who have loan

at the Penngridge branch

or customer-name (branch-name = Penngridge) (borrower-lam-number  
borrower-number (borrower-loan))

e.g. Find the names of the students whose CGPA is greater than 9.0.

Material join : is a binary operation that allows to combine certain selections and a cartesian products into one operation.  
symbol  $\bowtie$  (M)

steps: 1: Cartesian products of arguments

i.e.,  $r \bowtie s$

2. selection forcing equality on those attributes that appear in both <sup>relational</sup> schema.

3. Removes duplicates rows.

e.g.  $R = (A, B, C, D)$      $S = (E, B, D)$

• Result schema =  $(A, B, C, D, E)$

$r \bowtie s$  is defined

$\Pi_{r.A=r.B=r.C=r.D=r.E} (r \bowtie s) = s.B^{-1} r_0 D = s.D(r \times s)$

Q. find the names of all customer who have a loan  
get the bank and the loan amount  
get the bank branch details  
get the details of the customers who have a loan  
and calculate the total amount of loans  
with the help of function and aggregate functions

### Extended Relational Algebra open

Generalized projection: extend the projection open by allowing arithmetic function to be listed in the projection list.

$$\Pi_{f_1, f_2, \dots, f_n}^E$$

~~20/2/18~~  
② Aggregate function  $f^n$  (E)  
 $g_1, g_2, \dots, g_n$   $f_1(A_1), f_2(A_2), \dots, f_n(A_n)$

E → stands for any relation  
G, G<sub>1</sub>, ..., G<sub>n</sub> → is a list for grouping the expression and can be left empty.

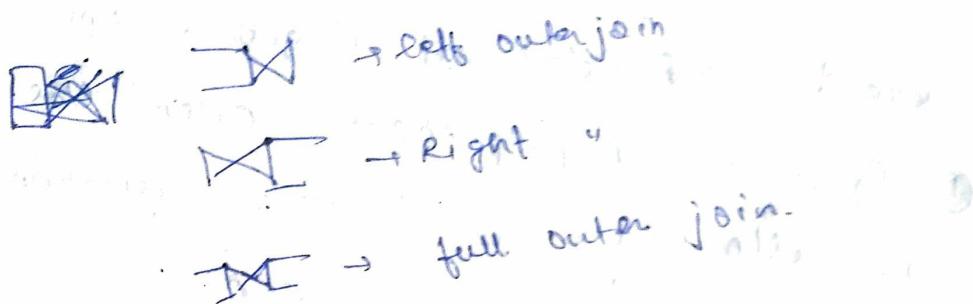

$f_1, \dots, f_n \rightarrow$  aggregate f's  
 $A_1, \dots, A_n \rightarrow$  are attributes

g → calligraphic g.

e.g; find the sum of the salary from emp table job wise.

$$g_{\text{sum(sal)}}(\text{emp})$$

3) Outer joins: Outer joins -> extension of the join operation that avoid loss of information. It computes the join and then add the tuple from one relation that does not match the tuple in the other relation to the result of the join.

Theta join: it uses any of the comparison operators after performing the cartesian product!

$$R \bowtie_{\theta} S \vdash \overline{\theta} (R \times S)$$

e.g.

Rel<sup>n</sup> Algebra

Rel Calculus

- Transaction: a unit of program execution that access or modify the data item

properties of transaction : A, C, I, D.

21/2/18

## Part II - DBMS

### Query Processor :

- DDL interpreter: It interprets DDL statements and records them in the data dictionary.
- ii) DML compiler & organiser: It translates DML statements into low level instructions that the query evaluation engine understands.
- iii) Query evaluation engine: creates low level instruction, generated by DML compiler.
- iv) Embedded DML pre-compiler: It converts DML statements embedded in an application program into normal procedure call in the host language (like C, C++, COBOL)

### Storage Manager:

- i) Buffer Manager: fetches data from disk storage to main memory and decide what data to cache in the main memory
- ii) file Manager: manages allocation of disk space and manage data structure used to represent information stored on disks.
- iii) Transaction Manager: ensures db consistency and concurrent transaction are executed without any conflict or system failure.

~~Authorization and Integrity Manager~~: Checks user to access data and ensures integrity constraints.

- iv) Disc storage: Data contains the actual data files. → data dictionary stores the meta data and the schema of the DB.  
→ Indices provide faster access to data items.  
→ statistical data provides data for reporting frequently used data.

Conversion of E-R model  
to PDL scheme

23/2/2018

## Steps of data Base design

- ① characterise the data needs of the perspective user and prepare user's requirement specification.
- ② Use a data model and translate the requirement to a conceptual schema which provides the detailed overview of the enterprise
- ③ Examine the schema to remove inconsistency and redundancy
- ④ Decide how to group attributes to form table using ER models and normalisation
- ⑤ Review the schema to ensure that it meets the functional requirement.
- ⑥ Implementation involves two design phases
  - logical design:  
High level schema is converted to data models
  - physical design:  
The physical aspects like, file organisation and internal storage structure are specified

## Modification of the DB

- Deletion
- Insertion
- Updation

- Deletion: Removes tuples from the DB but does not display the result.

$$r \leftarrow r - E \quad r: \text{relation (table, view)} \\ E: \text{relational algebra expression}$$

e.g; delete all account records from perryridge branch.

$$\text{account} \leftarrow \text{account} - \{ t \mid \text{branch-name} = "perryridge" \}$$

e.g; delete all known records with amount in the range of 0-350.

$$\text{loan} \leftarrow \text{loan} - \{ t \mid \text{amt} > 0 \text{ or amt} \leq 350 \}$$

- Insertion: to insert data into a set a tuple is specified to be inserted or a query is specified whose results is the set of tuples to be inserted.

$$r \leftarrow r \cup E \quad r: \text{relation (table, view)} \\ E: \text{expression specifying that}$$

e.g; insert information in the DB specifying that smith has \$1200 in account A-993 at perryridge branch.

$$\text{account} \leftarrow \text{account} \cup \{ ("A-993", "perryridge", 1200) \}$$

$$\text{depositor} \leftarrow \text{depositor} \cup \{ ("smith", "A-993") \}$$

e.g; insert Alex staying in 25 downtown and city RedRoad and the loan no is 8427.

$$\text{customer} \leftarrow \text{customer} \cup \{ ("Alex", "25Downtown", "RedRoad") \}$$

$$\text{borrower} \leftarrow \text{borrower} \cup \{ ("Alex", "8427") \}$$

- Updation: is used to change a value in the tuple without changing the other values of the tuple.

$\pi_{F_1, F_2, \dots, F_k}(\tau)$

e.g., make interest payment by increasing all account balances by 5% (0.05).

account  $\in \Pi$

(account)

account\_no, branch\_name, account\_balance

e.g.; Pay all account with balance over \$10000 6 percent interest and pay all other 5 percent.

account  $\leftarrow \Pi_{\text{account_no}, \text{branch_name}, \text{acc_bal} \times 1.06 \text{ acc_bal} > 10000}$

account  $\in \Pi$

(account)

account  $\leftarrow \Pi_{\text{account_no}, \text{branch_name}, \text{acc_bal} \times 1.05 \text{ acc_bal} \leq 10000}$

e.g.; Give all employees of first Bank Corporation a 10 percent salary raise.

work  $\in \Pi$

(work)

(company\_name = "FBC")

works  $\leftarrow \Pi_{\text{per_name}, \text{company_name}, \text{salary} \times 1.10}$

e.g.; find the name of supplier who supply red part

parts  $\in \Pi$

(Parts))

(catalog\_id (color = "Red"))

parts  $\leftarrow \Pi_{\text{supplier}}$

catalog\_id  $\in \Pi$

catalog\_id  $\leftarrow \Pi_{\text{catalog_id}}$

catalog\_id  $\leftarrow \Pi_{\text{catalog_id}}$

## Relational Algebra

1. It is a procedural language
2. It specifies how to open the query results
3. Describe the order in which operations have to be performed
4. It is closed to programming language
5. It is difficult for the use of non experts

## Relational Calculus

- 27/1/18
1. declarative lang.
  2. specify what result we have to obtain
  3. Does not specify order of operation
  4. closed to natural lang.
  5. easy for the use of non-experts.

## Relational Calculus (TRC, DRC, QBE)

### Relational Calculus

- \* i) TRC (Tuple Relational Calculus)
  - It is a non-procedural declarative lang. which describes the desired information without giving a specific procedure to obtain that information

$\{ t \mid P(t) \}$   
projection  
condition.

$t$  is the set of all tuples such that  
 the predicate  $P$  is true for  $t$ .

$t$  - tuple variable

can be classified as

- free variable or
- bound variable

- a variable is said to be free unless it is quantified by  $\exists, \forall$ . (i.e; without any  $\exists, \forall$ )

- Any tuple variable with  $\forall/\exists$  is condition  
 is called bound variable.

Variable used is cond' called tuple variable).

Q. select those employee from employee table  
whose salary is greater than 10K  
 $\{ t | \text{employee}(t) \wedge t.\text{salary} > 10K \}$

a. select all tuple from employee table who  
work for department id = 10

$\{ t | \text{employee}(t) \wedge t.\text{id} = 10 \}$

\* select the fname and lname from  
employee where salary is greater than  
5k.

$\{ t.\text{fname}, t.\text{lname} | \text{employee}(t) \wedge t.\text{salary} > 5k \}$

Q. select the birthdate(b.date) and address  
of those employee where fname is john and  
lname is Smith.

$\{ t.\text{b.date}, t.\text{address} | \text{employee}(t) \wedge t.\text{fname} = \text{john} \wedge t.\text{lname} = \text{Smith} \}$

## 2) DRC (Domain Relational Calculus):

- It uses a list of attributes to be selected from the relation rather than whole tuple and is also a declarative language.

Notation:

$$\{ \langle x_1, x_2, \dots, x_n \rangle \mid p(x_1, x_2, \dots, x_n) \}$$

$x_1 - x_n \rightarrow$  domain variable

$p \rightarrow$  formula

- the result is a set of tuples  $x_1 - x_n$   
that make the DRC formula true.

## 3) QBE (Query By Example)

- It is an abstraction between the user and the actual query language where a parser is used to convert the user actions into DML command. It provides a simple GUI to enter queries in terms of the data and the command the user wants to perform.

Employee (fname, lname, address, ~~duo~~)

Department (Dname, dnumber)

a. find the name and address of all employees who work for research department

R.A:

T

employees

## A Relational DB Design Guidelines

- A. Semantics of the relational attributes.  
Each tuple in a rel should represent one entity and the attributes of other entities should not be mixed in the same rel. Only foreign keys should be used to refer to other entities.

- B. Reduce the redundant values in the tuples

minimise the storage space used by the base relation and design a schema which does not suffer from insert, update and delete anomaly.

e.g. examples of

delete, update  
insert, update  
anomaly.

problems:

- i) insertion anomalies
- ii) Deletion anomalies
- iii) updation anomalies.

[C] Reducing null values in tuples.  
Avoid placing attributes in a base relations whose values may frequently be null as null values lead to wastage of storage space, problems with join operation and

mis-interpreation of attributes. problem: wastage of storage space, difficulty in applying aggregate functions.

[D] Disallowing the possibility of generating spurious tuples by designing a schema that can be joined with equality constraints.

### Functional Dependencies (F.D.)

defn:- Is used to specify formal measures of the goodness of the relationship design.

- A set of attributes  $X$ , functionally determine  $Y$  if the value of  $X$  uniquely determines  $Y$ .

for any two tuples  $t_1$  and  $t_2$  in any ref. instance  $r(R)$ : if  $t_1[X] = t_2[X]$  then  $t_1[Y] = t_2[Y]$

e.g;

def  
 $t_1$   
" "  $t_2$

e.g.c

$X \rightarrow Y$

e.g; examples of FD constraints:

e.g. project no. determines project name and location

project number  $\rightarrow \{ \text{pname, plocation} \}$

LSSM, project no.  $\rightarrow \{ \text{hours} \}$

### Properties of f<sup>n</sup>al dependencies

- the set of attributes  $X$  is called the LHS of the f<sup>n</sup>al dependency (F.D) and the set of attributes  $Y$  is called RHS of F.D.

- It is defined explicitly by someone who knows the semantic of the relation.

- New F.Ds can be derived from the existing ones.

- F.Ds are used to find the primary key

- if  $K$  is a key of relation  $R$  - then

$K$  functionally determines all the attributes of the relation.

- It specifies a constraint on all relationship instances.

## Inference Rules (IRs)

1. If  $x \in Y$  then  $X \rightarrow Y$  (Reflexive Rule)
2. If  $X \rightarrow Y$  then  $XZ \rightarrow YZ$  (Augmentation Rule) { Armstrong Axioms
3.  $\{X \rightarrow Y, Y \rightarrow Z\}$  then  $X \rightarrow Z$  (Transitive Rule)
4. If  $X \rightarrow YZ$  then  $X \rightarrow Y$  (Decomposition Rule)
5.  $\{X \rightarrow Y, X \rightarrow Z\}$  then  $X \rightarrow YZ$  (Union rule)
6. If  $X \rightarrow Y, WY \rightarrow Z$  then  $WX \rightarrow Z$  (Pseudotransitive rule)

e.g., Reflexive Rule:

$X \rightarrow \text{partno}(NT203)$   
 $Y \rightarrow \text{part id}(203)$   
 $Y \sqsubseteq X$

As per Rule  
 $\text{part no} \rightarrow \text{part id}$

e.g.; Decomposition

$SSN \rightarrow \text{ename, telno}$   
then  $SSN \rightarrow \text{ename}$   
 $SSN \rightarrow \text{telno}$

Aggregation rule

$SSN \rightarrow \text{dept}$   
 $SSN, \text{ename} \rightarrow \text{dept, ename}$

Transitive rule

$SSN \rightarrow \text{ename}$   
 $\text{ename} \rightarrow \text{email id}$   
 $SSN \rightarrow \text{email id}$

Union rule

$SSN \rightarrow \text{ename}$   
 $SSN \rightarrow \text{tel no.}$   
 $SSN \rightarrow \text{ename, telno}$

Pseudotransit.

$SSN \rightarrow \text{ename}$   
 $\text{dept, ename} \rightarrow \text{manager}$   
 $\text{ename, SSN} \rightarrow$   
 $SSN, \text{dept} \rightarrow \text{manager}$

More Armstrong Axioms are said to be sound & complete. sound, bcoz a given set of FDs on any rel" R, if we can infer a new set of FD's from IR<sub>1</sub>, IR<sub>2</sub>, IR<sub>3</sub> it will hold good in every relationship instances of R and complete because, the closure of f (f. d's) can be determined from using only IR 1, 2, 3.

e.g; 1.  $X^+ = X$ ;

2. Repeat

for each f. D  $Y \rightarrow Z$  in f

do

$X^+ \supseteq Y$ , then  $X^+ = X^+ \cup Z$

until (There are no changes to  $X^+$ );

closure of F or  $F^+$

: F is a set of F. D, the set of all dependencies that include f as well as the new dependencies logically derived from the new dependencies logically derived from f is called closure of f. or  $f^+$

e.g;  $F = \{A \rightarrow B\}$

$\therefore$  using Transitive Rule  
we get new dependency  
 $A \rightarrow C$

$F^+ = \{A \rightarrow B\}$

$B \rightarrow C$

$A \rightarrow C\}$

$\therefore F^+$  is the closure of F or  $F^+$

ie  $R$  is a reln with attr  $X, Y$   
 for  $x \rightarrow y$

e.g;  $R = \{A, B, C, D, E, F, G, H, I, J\}$

$$F = \{AB \rightarrow C, A \rightarrow DE, B \rightarrow F, F \rightarrow GH, D \rightarrow IJ\}$$

$AB^+ \rightarrow \{A, B, C, D, E, F, G, H, I, J\}$ $A^+ \rightarrow \{A, D, E, I, J\}$ $B^+ \rightarrow \{B, F, G, H\}$ $F^+ \rightarrow \{F, G, H\}$ $D^+ \rightarrow \{D, I, J\}$
--

equivalence of FD's  
using cover

e.g;

$$F: \begin{aligned} A &\rightarrow C \\ AC &\rightarrow D \\ E &\rightarrow AD \\ E &\rightarrow H \end{aligned}$$

$$\begin{aligned} CA^+ &\rightarrow CD \\ E^+ &\rightarrow AH \end{aligned}$$

closure of  $F$  using  $G$

$$G: \begin{aligned} (A)^+ &\rightarrow A, C, D \\ (AC)^+ &\rightarrow AC, D \\ (E)^+ &\rightarrow EAHCD \end{aligned}$$

closure of  $C$  using  $G$

$$\begin{aligned} (A)^+ &\rightarrow A, C, D \\ (E^+)^+ &\rightarrow EHAD, C \end{aligned}$$

all dependency of  $F$  can

be also performed in  
closure of  $\wp F$  using  
 $G$ .

$$\therefore F \subseteq G$$

$$\therefore G \subseteq F$$

$$F = G.$$

$F$  equivalent to  $G$ .

all dependency of  $F$  can

be also performed in  
closure of  $G$  using  $F$

## ① Minimal set of functional dependency.

→ A minimal / canonical cover of a set of FD that is equivalent to  $\mathcal{F}$ .

- Let  $\mathcal{F}_B$  ( $X \rightarrow B$ ) where  $X, B$  is set of attributes then redundancy arises due to i)  $X$  or ii)  $B$  or iii)  $X \rightarrow B$  for redundancies.
- finding minimal cover / canonical cover

e.g., given,  $R(w, x, y, z)$

$$\mathcal{F} = \{ \begin{array}{l} X \rightarrow w \\ wz \rightarrow x \\ y \rightarrow wz \end{array} \}$$

① Decompose the dependency

$$X \rightarrow w$$

$$wz \rightarrow x$$

$$wz \rightarrow y$$

$$y \rightarrow w$$

$$y \rightarrow x$$

$$y \rightarrow z$$

"") remove the dependency which is not useful.

$$X \rightarrow w \rightarrow x^+ \rightarrow x \quad w \rightarrow y \rightarrow z \quad \text{not same so this dependency is essential}$$

$$wz \rightarrow x \quad (wz)^+ \rightarrow w, z, x, y \quad \text{same so this dependency is essential}$$

$$wz \rightarrow y \rightarrow z \quad (wz)^+ \rightarrow w, z, y \quad \text{not same so, essential}$$

$$(wz)^+ \rightarrow wz \quad (wz)^+ \rightarrow w, z, y \quad \text{not same so, essential}$$

$$y^+ \rightarrow yw \rightarrow z \quad \text{same}$$

$$y^+ \rightarrow yx \rightarrow z \quad \text{same}$$

$$y^+ \rightarrow yz \quad \text{not same}$$

$$y^+ \rightarrow yz \quad \text{same}$$

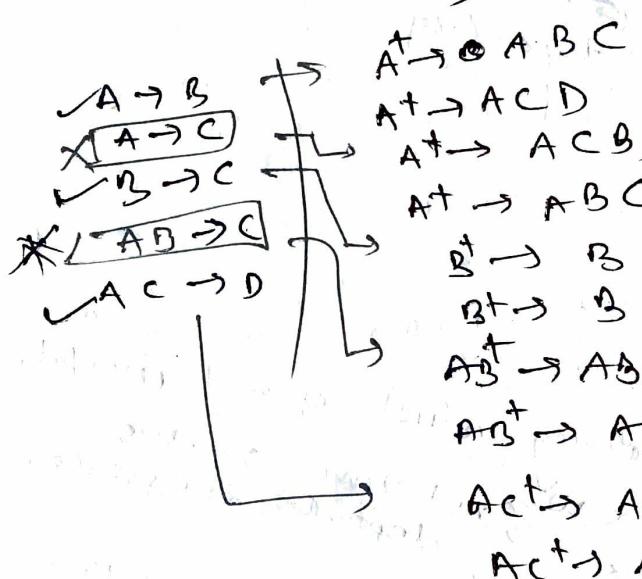

so essential dependencies are  
for  $wz \rightarrow y$

<del>wz</del>	<del>y</del>
$x \rightarrow w$	
$wz \rightarrow y$	
$y \rightarrow x$	
$y \rightarrow z$	

$w^t \rightarrow wzyx$
not same $w^t \rightarrow w$ (ignoring z)
no same $z^t \rightarrow z$ (ignoring w)

so they can not be ignored.

e.g.,  $F = \{ A \rightarrow BC$   
 $B \rightarrow C$   
 $AB \rightarrow C$   
 $AC \rightarrow D \}$

$A \rightarrow B$   
 $B \rightarrow C$   
 $AC \rightarrow D$

$AC \rightarrow D$

$(AC)^+ \rightarrow ACBD$

$(A + )^+ \rightarrow ABCD$

~~C~~

Act replaced  $\rightarrow$

$A \rightarrow B$   
 $B \rightarrow C$   
 $A \rightarrow D$ .

## ii) 2NF

- fully base
- Based on fully functional dependency

→ prime attribute (the attribute which is part of key)  
→ Non-prime attribute (" " " " not part of any key)

### fully functional dependency :

A f. D  $x \rightarrow y$  is called fully f. D if  
removal of any attribute from  $x$   
leads to removal of any attribute from  $y$ .  
The dependency does not hold any more.

But if the f. D  $x \rightarrow y$  still holds after  
removal of some attribute from  $x$  then it is  
called partial f. D.

Partial dependency: if proper subset of candidate key determines non-

" A rel<sup>n</sup> schema R is called in 2NF, if  
every non-prime attribute of R is not partially  
dependent on key of R "

A Rel<sup>n</sup> is in 2NF iff  

- It is in 1NF
- It has no partial dependency.

key for the  
notation

### The Goals of Normalization

- i) satisfy the attribute preservation property
- ii) normalization must satisfy the dependency preservation property.
- iii) satisfy the lossless join property or non-additive join property.

preserves  
\*\*\*\* goals of normalization

- satisfies :-
- Attribute preservation
- dependency preservation
- lossless join property (or additive join).

non-trivial dependency: if functional dependency  $x \rightarrow y$  holds true when  $y$  is not a subset of  $x$  then it is called a non-trivial f'd dependency. (i.e.,  $x \rightarrow y$  but  $y \not\subseteq x$ )

3NF: 3rd Normal form; Based on transitivity property.

A set<sup>n</sup> are in 3NF if, whenever a non-trivial f'd dependency  $x \rightarrow y$  holds in R then either  $x$  is a super key of R or  $y$  is a prime attribute of R. (i.e., for every non-trivial FD one of the above cond's should occur)

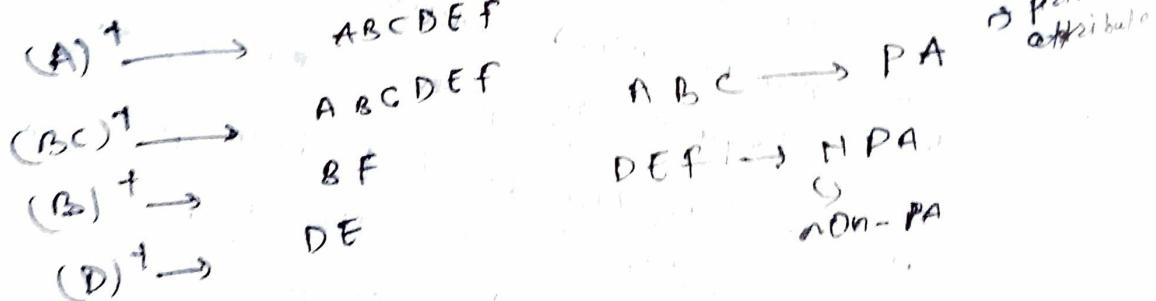

$$A \rightarrow BCDEF$$

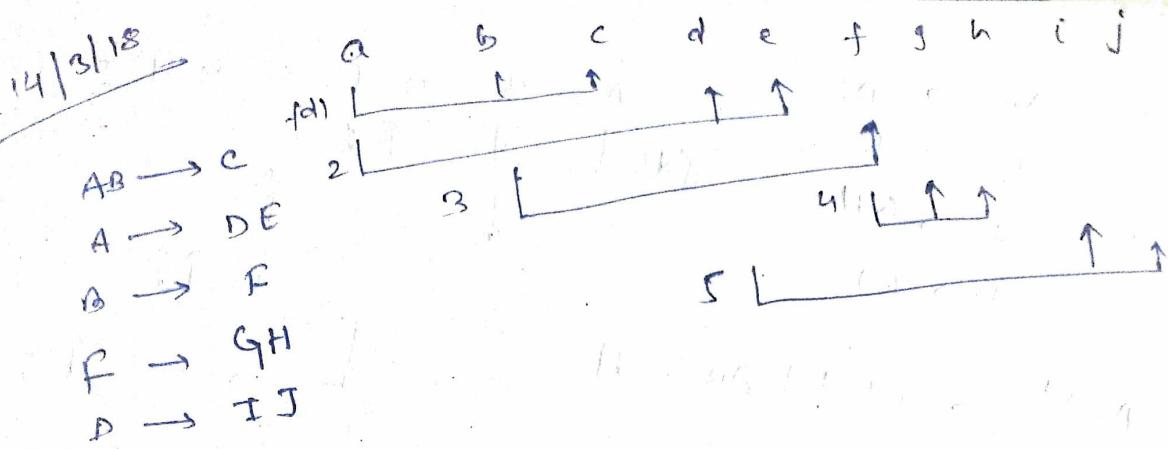

$$BC \rightarrow ADEF$$

$$B \rightarrow F$$

$$D \rightarrow E$$

	A	B	C	D	E	F
fd1		↑	↑	↑	↑	↑
fd2		↑	↑	↑	↑	↑

~~BCNF~~ (Boyce Codd Normal Form):  
does not guarantee about dependency  
preservation property

- A Reln R is said to be in BCNF if
- there is a F.D  $x \rightarrow y$  free then x is a sk. of R. (i.e; for every non-trivial F.D  $x \rightarrow y$ , x is a super key).

e.g.;  $F = \{B \rightarrow C, C \rightarrow A, C \rightarrow D\}$

## → Multi-value Dependency

A MVD  $x \rightarrow y$  specified on a rel<sup>n</sup> R specifies the constraint that if two tuples  $t_1$  and  $t_2$  exist such that  $t_1[x] = t_2[x]$  then there must exist tuples  $t_3$  and  $t_4$  such that  $t_1[x] = t_2[x] = t_3[x] = t_4[x]$ ,

$$\rightarrow t_1[y] = t_3[y] \text{ & } t_2[y] = t_4[y]$$

$$\rightarrow t_1[z] = t_3[z] \text{ & } t_2[z] = t_3[z]$$

$$\rightarrow t_1[z] = t_4[z]$$

4NF

A rel<sup>n</sup> R is said to be 4NF w.r.t a set of dependencies F iff for every nontrivial MVD  $x \rightarrow y$ ; x is a super key of R.

## TRANSACTION :

It is a unit of program execution that accesses and possibly updates various data items.

- Transactions are written in HLL basically SQL and Java.

i) Transaction concept:  
has a property called ACID property:

- A → Atomicity
- C → consistency
- I → Isolation
- D → Durability

- Atomicity ensures that all the steps of the transaction are executed or none is executed.
  - It is handled by transaction management component.
- Consistency: ensures that the execution of the transaction does not change the consistency of a DB and it is managed by the application programmer.
- Isolation: ensures that when multiple transaction are executing concurrently each transaction must be unaware of other concurrently executing transaction and handled concurrency controlled component.
- Durability: ensures that once the transaction completes successfully, the changes it has made to the DB persists even if there is syst. failure.
  - and managed by the secony management component.

28/3/18

concurrency : A DB must provide a mechanism that controls  
 will ensure all possible schedules are conflict-free or view serializable.  
 - recoverable  
 - preferably cascade-less schedules

techniques:

- lock-based protocols
- timestamp based

lock-based : A lock is a mechanism to control concurrent access to a data item.

lock-based (exclusive) lock : item/data can be both read and written

1. X-mode (exclusive) lock : item/data can be both read and written

LOCK-X(A)

2. Shared(s) mode lock : data item

can only be read.

LOCK-S(A)

\* locks are managed by concurrency control manager.

A trans can be granted

or lock on a specific data item if the requested locks

compatible with the locks already existing on the data item by other trans.

- If a lock can't be granted then the transaction is made to wait until the locks

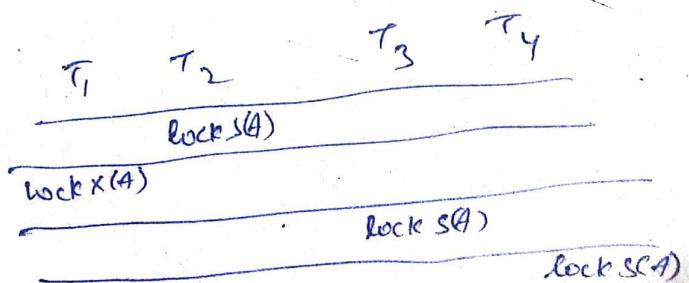

are released

S	X
true	false
false	false

Disadvantage of lock-based:

→ dead lock : the situation in which two or more trans are waiting for one another to release locks.

→ starvation :

if a trans<sup>n</sup> Ti has a shared mode lock on data item A and another trans<sup>n</sup> Tj request an exclusive mode lock on same data item. Then Tj has to wait until Ti releases the lock. Meanwhile, if a third trans<sup>n</sup> Tk request a shared mode lock on the same data item, then Tk is granted access and Tj has to wait further.

SOP to starvation: when a trans<sup>n</sup> request an incompatible lock then it is put on the ready queue and the other trans<sup>n</sup> requesting compatible lock are also put on the same queue below the transaction requesting incompatible lock.

Two phase locking protocol: simply ensure serializability but not cascading scheduling

phase 1: Growing phase

→ trans<sup>n</sup> may obtain locks

→ trans<sup>n</sup> may not release any locks

phase 2: Shrinking phase

transaction may release the lock but it won't obtain new locks

strict 2-phase locking protocols:

the trans must hold objects x-lock  
till it commits all aborts

Rigorous two phase locking protocols:

it holds all the lock till it commit all  
aborts.

KSE

30/3/18

lock conversions:

in the 1st phase of lock-conversion:-  
growing phase { can acquire lock-S on any data item  
" " " " lock-X  
" " " " lock S → X (upgrade)

shinking phase { can release lock-S  
" " " " lock-X  
" " " " X → S (downgrade)

→ lock point : point in the schedule where  
a transaction has obtained at final lock i.e;  
at the end of the growing phase and before  
the beginning of the shrinking phase.

DEADLOCK :

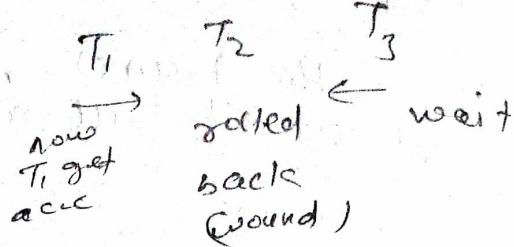

- prevention
- detection
- Recovery

- prevention:

i) wait-die scheme  
(non-preemptive)

T <sub>1</sub>	T <sub>2</sub>	T <sub>3</sub>
wait	wait	rolled back
continue		

2) wait-wound scheme  
(pre-emptive)

- Detection of deadlock:-

This protocol will initially allocate sys.  
to enter to a deadlock state and try  
to recover from it.

wait-for-graph

$$\text{pair, } G = (V, E)$$

an edge is created when a trans<sup>n</sup> T<sub>i</sub> requests  
an data item from trans<sup>n</sup> T<sub>j</sub>. The edge is  
removed when T<sub>j</sub> releases the data item.

Dead lock Recovery: wth one or more trans<sup>n</sup> is  
rolled back to break the cycle in the wait-

for graph. Actions taken are:-  
i). selection of victim (i.e; which trans<sup>n</sup> will be rolled back)  
ii). the selection of victim will be done on

following criteria:-

- a trans<sup>n</sup> which has completed for lesser time
- the one which has used less no. of locks.
- the one which has least dependency with other transaction.

2) Roll back:-

i) complete roll back (Restart the transaction again)

ii) Partial roll back i.e; roll back

as far as necessary to break tie,  
dead lock.

- (b) 3) starvation: if the same token is selected for victim repeatedly then it is said to be starved. To resolve starvation, there must be a threshold value which indicates how many times a particular token can be selected as victim.
